## CHAPTER I

## INTRODUCTION

An unsafe narrow bridge is one that contributes to property damage, personal injury, or fatal accidents. The definition of what constitutes a hazardous narrow bridge and what are the specific bridge features that contribute most to making it hazardous are difficult to determine, primarily because of the lack of the documentation of factors that affect accidents at a narrow bridge site. Factors suggested in related studies include the bridge geometry, bridge structure, geometry of the approaching roadway, traffic volume, vehicle mix, driver error, and others. The technology exists for ameliorating bridge accident problems by constructing safer highways, bridges, and control and warning equipment. Because control and warning methods are passive measures, engineers prefer to improve active measures such as bridge geometry or structures or highway geometry to reduce accident rates or to reduce their severity. For instance, recent improvements in bridge rails are intended not only to prevent penetration by small and large size vehicles but also to provide safe redirection for such vehicles. Therefore, a subjective evaluation of bridge safety by engineers would be expected to emphasize these factors.

The Bridge Safety Index (BSI), which is such an approach to the evaluation of bridge safety, was developed by the Texas Transportation Institute. (1)* On the basis of data collected and the experience of the re-

[^0]searchers, they assigned weights to ten factors which were considered to contribute to bridge hazards, and the Bridge Safety Index was defined as the sum of these ten individual bridge site rating factors. Although the first attempt at such a definition was successful, some problems exist in the current Bridge Safety Index. For instance, it would be interesting to determine whether the weights on each of the ten factors can be found by more objective means. If it can be done, it would almost certainly show that each of the ten factors would have a different weight in determining the BSI. The Texas Transportation Institute undertook a study of narrow bridges to see if the Bridge Safety Index could be improved.

The purposes of this study are as follows:

1. Re-establish a Bridge Safety Index based on discriminant analysis,
2. Appraise the weights on the selected factors which would have a high degree of contribution to accident rates, and
3. Identify, using the new Bridge Safety Index, the potentially hazardous bridge.

The Statistical Analysis System (SAS), a package of computerized statistical procedures, is used to perform the majority of this study, and data utilized for analysis is taken from existing files of 78 bridge sites within Texas.

The Texas Transportation Institute conducted a comprehensive narrow bridge safety program, including a method of determining a priority rating for the improvement of bridges having restricted width. The data collected at 25 bridge sites throughout the U. S. was surveyed for bridge and highway geometries, traffic speed, bridge structures, traffic volume, surrounding circumstances, and others. The Bridge Safety Index (BSI) was estimated in terms of ten factors which were considered to contribute to hazardous bridge conditions. Weights were assigned to these ten factors, and the Bridge Safety Index was defined as the sum of these ten individual rating factors. As a result, the Bridge Safety Index (BSI) could be expressed as (1)

$$
\begin{equation*}
B S I=F_{1}+F_{2}+F_{3}+\ldots+F_{10} \tag{1}
\end{equation*}
$$

where $F_{1}=$ clear bridge width,
$F_{2}=$ bridge lane width/approach lane width,
$F_{3}$ - guard rail and bridge rail structure,
$F_{4}=$ approach sight distance/85\% approach speed,
$F_{5}=100+$ tangent distance to curve/curvature,
$F_{6}=$ grade continuity,
$F_{7}=$ shoulder reduction,
$F_{8}=$ volume/capacity ratio,
$F_{9}=$ traffic mix (primarily the percent trucks), and
$F_{10}=$ distractions and roadside activities.

With the exception of $F_{1}$, which is determined from Figure 1, all other nine factors are evaluated by relying on Table 1 . Also, the factors $\mathrm{F}_{1}$, $F_{2}$, and $F_{3}$ are rated from 0 to 20 , and the remaining seven factors are rated from 1 to 5. Thus, the most ideal bridge site conditions produced a BSI of 95 and a critically hazardous site had a value of 20 .

The report also described a method of determining the priority in making improvements in narrow bridges by using the BSI to rate planned corrective treatments. Accordingly, the priority index was defined as the ratio of the benefit to people that would be realized with a particular corrective measure divided by the total cost. A model for setting priorities presented by D. L. Ivey, et.al. was expressed as (1)

$$
\begin{equation*}
P I=\frac{\left(B S I_{A}-B S I_{B}\right) \times K A D T}{C} . \tag{2}
\end{equation*}
$$

where PI = priority index,
$B S I_{A}=$ Bridge Safety Index after treatment,
$B S I_{B}=$ Bridge Safety Index before treatment,
KADT = average daily traffic, in 1000 's, and
$C=$ cost of the treatment or bridge hazard improvement.
During 1978 and 1979, a study to evaluate the BSI and the priority index was conducted by the Texas State Department of Highways and Public Transportation at 78 selected bridge sites within the State of Texas. Appendix I presents the results of each rating factor and of the BSI for each study bridge site. Also, the districts proposed a comprehensive safety program for each bridge site as summarized in Appendix II. However, a review of the recommendations for corrective treatments, and an

| F7 | 100 | 75 | 50 | 25 | None |
| F8 | 0.5 | 0.4 | 0.3 | 0.1 | 0.05 |
| F9 | Wide Discontinuities | NonUniform | Normal | Fairly Uniform | Uniform |
| F10 | Continuous | Heavy | Moderate | Few | None |

evaluation of the BSI and PI after treatment revealed that a problem existed in the definition of one or the other. For instance, a corrective treatment such as "Bringing and Maintaining Markings to High Level" can not be applied in a simple way to Table 1 to evaluate BSI after treatment. With no change in BSI due to the corrective treatment, the treatment would receive a zero priority index. The question immediately arises whether pavement markings affect bridge safety. Turner, in his dissertation (2), cited several publications which summarized how bridge safety was influenced by some corrective treatments. These included: (a) install delineators at bridge, (b) pavement edge marks at narrow bridge, (c) install or improve warning signs, and others. Because improvements $a, b$, and $c$ can not be rated directly by the current definition of BSI, it is reasonable to add more factors to the definition.

CHAPTER III
RESEARCH APPROACH

The preceeding review revealed that there are some limitations in determining and applying to the Bridge Safety Index presented by D. L. Ivey, et.al. (1) For these reasons, it was desirable to develop by statistical means an equation for the BSI which contains all previous variables in addition to those that rate explicitly the improvements that were planned by the Texas SDHPT so that a new BSI and new PI can be estimated. By using statistical analysis, it is expected that better parameters for modeling bridge safety could be found, and an evaluation of the significance of the individual variables in the BSI could be made. This requires the addition of more variables upon which the BSI may depend and by using statistical techniques develop a new equation for evaluating the Bridge Safety Index. Details of this development are described in the following section.

New Factors, $\mathrm{F}_{11}, \mathrm{~F}_{12}$
In order to avoid complicated variables and considering the improvements in hazardous bridge conditions that were recommended by 15 districts, only two factors, $F_{11}$ and $F_{12}$ were added as variables in this study of the BSI. The $F_{11}$ factor, paint marking, is defined as the combination of centerline, no passing zone stripes, edge lines, and diagonal lines on the shoulder of the pavement. The $\mathrm{F}_{12}$ factor, warning signs or reflectors, is defined in terms of narrow bridge signs, speed signs,
reflectors on the bridge, or black-white panels on the bridge ends. It is considered that these factors are effective in reducing the lateral movement of the vehicle, changing the vision of the driver, and controlling speed. These are also expected to contribute to a reduction in the probability of accidents, and thus should be included in the Bridge Safety Index.

Table 2 shows a way of determining the factor $F_{11}$ in the field which is separated into three main items, i.e. centerline and no passing zone stripes, edge lines, and diagonal lines. The nomogram shown as Figure 2, like the weighting factor $F_{3}$, is used to convert from the word descriptions to a quantitative value for rating the $F_{11}$ factor. Table 3 shows a way for evaluating the $\mathrm{F}_{12}$ factor which contains the narrow bridge signs, speed signs, reflectors, and black-white panels, or other markers. Engineering judgement will be used to convert the observed estimation into one of the descriptive terms. It should be noted that the rating of these two factors are assigned values from 1 to 5 in this study.

## Data Source

The data used for developing a new Bridge Safety Index were taken from data collected in 1978 and 1979 by the Texas Transportation Institute at the 78 bridge sites where corrective treatments were recommended in the 15 districts for the State of Texas. An initial evaluation to the factors of each bridge site was based on the field method (3) in which $F_{1}, F_{2}$, and $F_{3}$ are rated from 0 to 20 . The other factors are assigned ratings from 1 to 5 as shown in Appendix I. For the purpose of statistical analysis to obtain the significance in each factor, the

ratings with respect to each factor are constrained to have a maximum value of 5, i.e. all ratings are based on same unit, and the relative weights will be determined by statistical analysis. Because of this, the factors $F_{1}, F_{2}$, and $F_{3}$ are corrected appropriately by dividing by 4 , thus resulting in the same scale as the rest of the factors. In addition, the ratings of $F_{11}$ and $F_{12}$ are developed from the available slides of each selected bridge and from recommendations by each district. The final set of corrected data is shown in Table 4. These were the input data for the statistical analysis in this study.

## Discriminant Analysis

If data are collected on several variables from two or more groups of subjects and it is desired to describe the ways in which the groups differ on these variables, an approach to achieve this differentiation is called a discriminant function analysis. Its objectives involve (a) maximizing the discrimination among the groups in terms of their means by a linear combination of the variables, and (b) establishing the boundaries for the assignment of new individuals into one of the groups (4).

A general linear discriminant equation is expressed as

$$
\begin{equation*}
z=a_{1} x_{1}+a_{2} x_{2}+\ldots \ldots a_{n} x_{n} \tag{3}
\end{equation*}
$$

where $Z=$ discriminant score,

$$
\begin{aligned}
& a_{1}, a_{2}, a_{3}, \ldots \ldots a_{n}=\text { coefficients, and } \\
& x_{1}, x_{2}, x_{3}, \ldots . x_{n}=\text { independent variables. }
\end{aligned}
$$

The value of the a's in the discriminant equation are chosen so as to maximize the ratio of the variance of the means between groups to the variance within the groups, as defined in (5)

$$
\begin{equation*}
\frac{\text { variance between means on } Z}{\text { variance within group on } Z} \tag{4}
\end{equation*}
$$

In the development of the discriminant function, a subprogram of Statistical Analysis System called "DISCRIM" is used in this study.

## Discriminant Analysis Based on MBSI score

Before the "DISCRIM" procedure is used, it is required to assign all of the available bridges into two groups on some "a priori" basis, such as by defining each bridge as either "safe" or "hazardous," since it is assumed that only two groups exist. The problem arises as to how to define the bridges as "safe" or "hazardous." Initially, the criterion for this classfication was the assumption that all bridges with "a priori" MBSI (modified BSI from the original data) of 38.5 or above are "safe" bridges. The 38.5 figure was chosen because it lies between the two peaks as shown in Figure 3. A sequence of trial and error calculations is made, in which groups are assigned on the basis of an assumed boundary value of MBSI, and the probability of discriminating on that basis is calculated. The best boundary value of MBSI is the one that produces the highest probability of discrimination. By this means, a value of 38.75 was found to separate the two groups best. The final results are shown in Appendix III in which group "0" represents the assumed hazardous

Fig. 3. Distribution of Modified Bridge Safety Index and Initial Boundary Chosen for Classification
bridges and group "1" represents the safe bridges. Table 5 summarizes the coefficients of the linear discrimination function based on the criterion stated above. The discriminant equation thus developed defines a new Bridge Safety Index (BSI) which can be expressed as

$$
\begin{aligned}
\mathrm{BSI}= & 1.48 \mathrm{~F}_{1}+2.19 \mathrm{~F}_{2}+0.97 \mathrm{~F}_{3}+0.47 \mathrm{~F}_{4}+0.93 \mathrm{~F}_{5}+1.33 \mathrm{~F}_{6}+ \\
& 1.47 \mathrm{~F}_{7}+0.23 \mathrm{~F}_{8}+0.9 \mathrm{~F}_{9}+1.75 \mathrm{~F}_{10}+1.78 \mathrm{~F}_{11}+0.72 \mathrm{~F}_{12} \ldots
\end{aligned}
$$

The coefficients show the relative weight that is applied to each of the 12 factors. Thus, through discriminant analysis it has been found that all 12 factors have different significance in determining the MBSI. Determining the relative significance is one of the major objectives in this study. It is considered that Eq.(5), which was developed by discriminant analysis should be more a reasonable representation of a Bridge Safety Index than Eq. (1), which was developed subjectively by D. L. Ivey, et.al. This Eq.(5) will be used in a subsequent section of this report to determine a new priority index for bridge improvements.

## Discriminant Analysis Based on Accident Rate

The criterion for classification into safe and hazardous groups that was used above was an "a priori" MBSI score, which is, in itself, subjective. In an attempt to use a more objective means of discriminating between the two groups, it is of interest to use the accident rate (No. of Accidents/Yr./1000 ADT) as a criterion to classify bridges into two groups since such a criterion should be less subjective than that of BSI score. Generally speaking, it is assumed that the higher the BSI is,

Table 5. Coefficients Used with Discriminant Function Based on MBSI Score

| Variable | Coefficient |
| :---: | :---: |
| F1 | 1.48 |
| F2 | 2.19 |
| F4 | 0.97 |
| F5 | 0.47 |
| F7 | 1.33 |
| F8 | 1.43 |
| F9 | 0.93 |
| F11 | 1.75 |
| F12 | 1.78 |
| F9 | 1.72 |

the lower the accident rates should be. However, a question arises as to whether all of the selected factors have a relationship with accident rates. If the selected factors are strongly correlated with accident rates, the results of discriminating a safe from a hazardous bridge using such a criterion with discriminant analysis should give a more reliable Bridge Safety Index. For the moment, it is assumed that a relationship exists between the selected factors and accident rates. The available accident data for each selected bridge site from 1974 to 1979 was gathered from the Texas State Department of Highways and Public Transportation where it was available in their computer files on accidents. Appendix IV summarizes the accident data for each bridge site that was derived from these files.

The problem also arises in defining the boundary of the accident rates so as to assign bridge sites into safe or hazardous classes. Trial and error is used to determine this boundary value of accident rate, as was done previously with the MBSI. The distribution of accident rate date on these bridges is shown in Fig. 4. Unfortunately, the groups are not well discriminated even though several attempts were made. The results are shown as Appendix V. In this attempt, based on a boundary accident rate of $0.3175,38$ bridges are placed into group " 0 " in which there are 12 bridges misclassified (31.58\%); 40 bridges are classified into group "1" in which there are 9 bridges misclassified (22.5\%). Table 6 summarizes the coefficients to be used with the linear discriminant function for ABSI (or Accident-related Bridge Safety Index). The equation of ABSI based on the accident rate criterion can be expressed as

$$
\begin{aligned}
\text { ABSI }= & 1.92 F_{1}+0.07 F_{2}-0.17 F_{3}-0.50 F_{4}+0.28 F_{5}+0.0004 F_{6}+ \\
& 0.02 F_{7}+0.02 F_{8}-0.13 F_{9}+0.49 F_{10}+0.26 F_{11}-0.48 F_{12} \ldots(6)
\end{aligned}
$$

Fig. 4. Distribution of Accident Rate Data

Table 6. Coefficients Used with Discriminant Function Based on Accident Rates

| Variable | Coefficient |
| :---: | :---: |
| F1 | 1.92 |
| F2 | 0.07 |
| F4 | -0.17 |
| F5 | -0.50 |
| F6 | 0.28 |
| F8 | 0.0004 |
| F9 | 0.02 |
| F10 | 0.13 |
| F11 | 0.26 |
| F8 | -0.48 |

Eq.(6) is quite different from Eq.(5). Not only do negative signs appear in some of the factors but most of the coefficients reduce. Also, one might expect that there would be a large coefficient on $F_{1}, F_{2}$, and $F_{3}$ of the bridges studied. It is apparent in Eq. (6) that although $F_{1}$ is significant, $F_{2}$ and $F_{3}$ are only slightly significant. It is worth stressing the point that the evaluation of the ABSI based on Eq. (6) would cause a problem later in the determination of the Priority Index, since the value of ABSI after some recommended treatments would be higher than that of ABSI before treatments. However, Eq.(6) may be used as a reference for evaluating ABSI before treatment, although some drawbacks exist in using it to define the Priority Index.

## Multiple Linear Regression Analysis

An additional investigation is conducted to examine the effects of the selected 12 factors on accident rates at the 78 bridges. For this study, a simple linear multiple regression analysis is performed to determine which of the 12 factors, if any, are related to accident rates. The basic equation of linear multiple regression analysis can be expressed as (4)

$$
\begin{equation*}
\widehat{A R}_{i}=\alpha_{0}+\alpha_{1} F_{i 1}+\ldots \ldots+\alpha_{12} F_{i 12} \tag{7}
\end{equation*}
$$

where $\widehat{A R}=$ accident rate $=$ No. of Accidents $/ \mathrm{Yr} . / 1000$ ADT,

$$
\begin{aligned}
& \alpha_{0}, \alpha_{1}, \ldots \ldots, \alpha_{12}=\text { regression coefficients, } \\
& F_{1}, F_{2}, \ldots \ldots, F_{12}=\text { defined on preceeding pages, and } \\
& i=1,2,3, \ldots \ldots, 78
\end{aligned}
$$

It is desirable to observe the significance of each factor here. The results of analysis by a subprogram of the SAS System are summarized in Table 7. The values given in the Table 7 in which $P R>|T|$ indicates the probability that the variable should not be in the model. Thus, when a very small value (<0.05) appears, it shows that the independent variable significantly contributes to the accident rate.

The most significant findings from the results are summarized as follows:

1. Only $F_{1}$ (bridge width) can be termed a strong indicator on accident rates with linear multiple regression analysis.
2. The selected 12 factors have only a weak correlation with accident rates since the coefficient of determination, $R^{2}$ is a small value of 0.26 .

## Stepwise Regression Analysis

A better analysis of the relationship between the factors and accident rates is to employ the "STEPWISE" procedure in the SAS System. The purpose of this procedure is to extract the more highly significant variables to be used in the model. Sometimes several variables in the model at the same time may interact with one another and cause the really significant variables to be "concealed". Once some of the variables are deleted, the really significant variables are gradually revealed.

The "STEPWISE" procedure begins by finding the single variable that produces the highest correlation ( $\mathrm{R}^{2}$ ) with accident rates. Then the "STEPWISE" procedure calculates the F-statistic reflecting this variable's contribution to the model if it is to be included. If it is not

Table 7. Results from Linear Multiple Regression Analysis

| Variable | Coefficient | $P R>\|T\|$ | $\mathrm{R}^{2}$ |
| :---: | :---: | :---: | :---: |
| F1 | -0.256 | 0.0007 |  |
| F2 | 0.016 | 0.5735 | 0.2589 |
| F3 | 0.002 | 0.9352 |  |
| F4 | 0.041 | 0.4696 |  |
| F5 | -0.023 | 0.3013 |  |
| F6 | -0.034 | 0.1183 |  |
| F7 | -0.001 | 0.9630 |  |
| F8 | -0.024 | 0.6307 |  |
| F9 | -0.002 | 0.9544 |  |
| F10 | $\bullet-0.009$ | 0.7424 |  |
| F11 | -0.003 | 0.9222 |  |
| F12 | 0.016 | 0.7169 |  |
| Intercept | 1.715 | 0.0034 |  |

significant, the "STEPWISE" procedure stops at this stage. Otherwise, the "STEPWISE" procedure adds the variable that has the largest F-statistic to the model. After a variable is added, however, the "STEPWISE" procedure looks at all of the rest of the variables already included in the model and deletes any variable that does not produce an F-statistic which is significant at the 0.05 level (which is specified in this study). Only after this check is made and the necessary deletions accomplished can another variable be added to the model (6).

The results of the "STEPWISE" analysis are shown in Table 8 in which $F_{1}$ is a strongly significant indicator of the accident rate. These results also imply that among the selected 12 factors, $F_{1}$ and $F_{6}$ are the only ones that are significantly correlated to the accident rates. The linear regression model that contains $F_{1}$ and $F_{6}$ has a coefficient of determination ( $R^{2}$ ) of 0.226 .

| $R^{2}=0.2256$ |  |  |  |

## CHAPTER IV

## APPLICATION FROM ANALYSIS

There are two applications on the BSI developed in this study: (a) identify the potentially hazardous bridge, and (b) estimate the priority index. The main feature of the discriminant analysis is to assign bridges to either the safe or hazardous group on the basis of data that are related to the group. The estimation of the priority index follows the model presented by D. L. Ivey, et.al. The following section will illustrate these two applications.

## Identify the Boundary of the Potentially Hazardous Bridge

While the new BSI has been estabilished, the next objective in this study is the determination of the boundary score which will be used to classify a bridge into the safe or hazardous group. In accordance with the theory of linear discriminant analysis, the way to determine the boundary score is a half distance between the mean values of the group "1" (safe) and the mean values of the group "0" (hazardous), namely (7),

$$
\begin{equation*}
\frac{1}{2}\left(\overline{\mathrm{MBSI}_{1}}+\overline{\mathrm{MBSI}_{0}}\right) \tag{8}
\end{equation*}
$$

where $\overline{\mathrm{MBSI}_{1}}=$ the mean of MBSI for the assumed safe bridges, and
$\overline{M B S I_{0}}=$ the mean of MBSI for the assumed hazardous bridges. Table 9 shows the mean of each factor in Group "1" and Group "0", respectively. The mean value of MBSI for the safe bridge, which is obtained by substituting the mean value of each factor shown in Table 9

Table 9. The Mean of Group "1" and Group "0" for Each Variable.

| Variable | Group "1" (Safe) | Group "0" (Hazardous) |
| :---: | :---: | :---: |
| F1 | 4.894 | 4.742 |
| F2 | 3.219 | 2.467 |
| F3 | 2.063 | 1.151 |
| F4 | 5.000 | 4.658 |
| F5 | 4.625 | 3.474 |
| F6 | 4.475 | 3.342 |
| F7 | 2.150 | 1.579 |
| F8 | 4.575 | 4.342 |
| F9 | 3.350 | 2.842 |
| F10 | 3.725 | 2.579 |
| F11 | 2.200 | 1.316 |
| F12 | 2.075 | 2.368 |

into Eq. (5), is 47.93. The mean BSI for a hazardous bridge is 37.78 . The midpoint then is $\frac{1}{2}(47.93+37.78) \approx 42.85$. Thus the classification rule is: a bridge is more like a safe bridge if its value of MBSI is above 42.85 and more like the potentially hazardous bridge if MBSI is below 42.85. An engineer may use this boundary score to assign a bridge into the group it most resembles and then propose an appropriate corrective treatment. In addition, if the MBSI of a bridge has an unsafe score (<42.85) it indicates that treatment is necessary, and in some cases, urgent. Also, the lower an MBSI score is below the boundary value, the higher its ranking is likely to be in determining priorities for corrective treatment.

## Estimation of Priority Index

One of the major features of developing a Bridge Safety Index is the determination of the priority ranking for the corrective treatment of a bridge. Basically, a model of the Priority Index here is following the one proposed by D. L. Ivey, et.al. (1). Table 10 presents a Priority Index calculation for some of the study bridges selected from seven districts in the State of Texas. All ratings after treatments are developed from recommendations by each district and from the available slides made by the Texas Transportation Institute in the field. One of the 78 study bridges is evaluated in detail below.

Bridge Site - Tarrant 220, 2C; District 2.
Before treatments, MBSI is a value of 45.05 (see also Table 4). According to recommendations of the district, the following corrective measures should be taken:

Table 10. Priority Index for Selected Bridge Sites

| Bridge Site | $\mathrm{BSI}_{\mathrm{a}}$ | BSIb | ADT | COST | PI |
| :---: | :---: | :---: | :---: | :---: | :---: |

| 20H--Liberty 146 | 54.94 | 46.53 | 1,400 | 31,000 | 0.38 |
| 20I--Hardin 101 | 51.76 | 45.78 | 7,000 | 21,000 | 2.00 |

1. bring and maintain paint markings to high level,
2. place diagonal markings on the right shoulder of both approaches, and
3. place edge lines on approaches and across the bridge. On the basis of above recommendations and rating factor criteria, only $F_{11}$ would be changed and has a value of 5 . After substituting all rating factors into Eq. (5), a value of MBSI with 52.17 is obtained for after treatments and the Priority Index using the calculation shown in Eq. (2) is 61.2.

## CHAPTER V

CONCLUSIONS AND RECOMMENDATIONS

## Conclusions

A successful method using discriminant analysis to evaluate a BSI has been presented in Chapter III. The discriminant function (BSI) based on the modified Bridge Safety Index score criterion has also been shown in Eq.(5). It should be noted that the new Bridge Safety Index was obtained from discriminant analysis by.assuming that a linear combination of the variables can properly distinquish between safe and hazardous bridges. This assumption is correct only under the following conditions:

1. the variance and covariances should be the same in both groups, and
2. the variables are multivariate normal.

If the above conditions are not met, non-parametric or non-linear discriminant analysis is more appropriate. In addition, the data is classified by an "a priori" score criterion into two groups. This inevitably leads to a misclassification of the data. The selected factors used in analysis have been assumed to be representative of bridge safety, and the score developed from these factors is assumed to be meaningful. Despite the restrictions mentioned above, the prediction results obtained from discriminant analysis are encouraging. It is also believed that this approach is a step further in the rationalization of a Bridge Safety Index for narrow bridges.

A promising evaluation of the Bridge Safety Index from the point of
view of accident rates has been shown in Eq.(6). However, the factors that are used in such an ABSI should be those that can be shown to contribute significantly to accident rates. As mentioned in Chapter IV, only $F_{1}$ and $F_{6}$ were found to be involved in accident rates through the "STEPWIEミ" regression analysis. However, the safety of narrow bridges is known to involve other factors than $F_{1}$ and $F_{6}(1)$. In addition, it should be pointed out here that in using multiple regression or stepwise regression analysis it is important to use large samples. Accordingly, the sample size in multiple regression or stepwise problem should be 100 or at least 20 times the number of variables (4). This is also one of the reasons that Eq.(6), which is based on an accident rate criterion used with discriminant analysis, cannot be recommended for use as an accidentrelated Bridge Safety Index, at the present time. It is the conviction of the author that if a sufficient quantity of data were available to allow such an analysis to be made then the resulting ABSI would be a superior method of rating bridge safety.

## Recommendations

The following recommendations are made concerning further steps to develop an improved Bridge Safety Index for narrow bridges.

1. It is necessary to collect more bridge site data for analysis, especially at narrow bridge sites, where the bridge width is less than 24 feet. The width of most of the 78 bridges used in this study are greater than 24 feet. It is believed that an evaluation of BSI would be more reasonable by discriminant analysis based on the same geometric and structural conditions of the bridge site.
2. It is desirable to collect more comprehensive accident data for each bridge site. Thus, on the basis of accident data the appropriate factors contributed to bridge safety can be made by statistical techniques. With these kinds of data being available, the Bridge Safety Index could be related not only to accident rates, but to their severity. Including severity of accident as a criterion for classifying bridges as safe or hazardous will probably make bridge structural and geometric conditions more important in determining an ABSI. Finally, the method of linear or non-linear discriminant analysis could be performed based on accident rates.

## APPENDIX II

# Summary of Recommendations for Corrective Treatments from Districts of Texas 

1. Bring and maintain paint markings to high level
2. Place edge lines on approaches and across the bridge
3. Place diagonal markings on right shoulder of both approaches
4. Mark for no passing zones
5. Install object marking
6. Install narrow bridge sign
7. Install reflective markings on rails
8. Block out approach rails to face appron curb
9. Tie approach rails to bridgerails
10. Bring approach rails up to standard
11. Block out bridge rail
12. Place $W$-section on bridge rails
13. Remove large trees (or historical marker)
14. Use herbicide (Vegetation control)
15. Relocate field road
16. Clean R.O.W. under bridge
17. Install adequate approach rail to deny acess near bridge

## ACCIDENT-RELATED BRIDGE SAFETY INDEX

2:04 FRIDAY, NOVEMBER 12, 1982
DISCRIMINANT ANALYSIS CLASSIFICATION SUMMARY FOR CALIBRATION DATA: WORK.BRIDGE

GENERALIZED SQUARED DISTANCE FUNCTION:

[^1]POSTERIOR PROBABILITY OF MEMBERSHIP IN EACH GROUP:
$\operatorname{PR}(J \mid X)=\operatorname{EXP}\left(-.5 D_{J}^{2}(x)\right) / \underset{K}{\operatorname{SUM}} \operatorname{EXP}\left(-.5 D_{K}^{2}(x)\right)$
NUMBER OF OBSERVATIONS AND PERCENTS CLASSIFIED INTO GROUP:
FROM
GROUP
$68 \quad \begin{array}{rrrr}26 & 12 & 38\end{array}$
$\begin{array}{rrr}9 & 31 & 40\end{array}$ $22.50 \quad 77.50 \quad 100.00$
$\begin{array}{rrr}35 & 43 & 78 \\ 4.87 & 55.13 & 100.00\end{array}$
$0.4872 \quad 0.5128$

[^0]:    *Numbers in parentheses refer to the corresponding item in the list of references.

[^1]:    $D_{J}^{2}(x)=(x-\bar{x})^{\prime} \operatorname{cov}^{-1}(x-\bar{x})_{J}-2 \operatorname{LNPRIOR}$
